

Value Type Assignment & Reference Type Assignment

Objects

String
Array

Value Type Assignments

```

public static void main(String[] args) {
    int x = 500; // constant
    int y;
    y = x; // variable
    System.out.println(x);
    System.out.println(y);
    x = 1000;
    System.out.println(x);
    System.out.println(y);
}
    
```

Memory mapping

reference

Stack

Heap

Notes

In value type assignment, variables always take the new set of value / copy of variable value altogether.

Reference Type Assignment

type = primitive object
Changing address

(create a copy of value)

```

public static void main(String[] args) {
    Developers karthik = new Developers();
    karthik.name = "Karthik";
    karthik.empId = 1001;
    karthik.salary = 50000;
    System.out.println(karthik);
    Developers saiAvena = (karthik);
}
    
```

RTS

Heap

Notes:

The value assignment will be address of the reference type i.e. address of the reference variable is stored as a value to it.

Types of Variables

There are 3 variables

- 1) Local i.e. automatic variables
- 2) Instance [fields]
- 3) Static [class variables]

Local Variable

- 1) local variables are declared inside the method
- 2) memory is allocated inside the stack
- 3) No default values will be assigned by the JVM

④ We cannot use local variables without initialising the value

⑤ Memory will be deallocated while the control comes out of the method

Instance Variable

- 1) Instance variables are declared outside the method & inside the class
- 2) memory is allocated inside the Heap Area
- 3) Default values will be assigned by the JVM (while allocating memory)

④ we can use instance variables without initializing any value

④ Default value for all data type

⑤ Memory will be deallocated by the garbage collector, when there is no reference to the object

```

static void add() {
    int a = 10;
    int b = 20;
    System.out.println(a+b);
}

public static void main(String[] args) {
    add();
    // ...
}

```

Local Variable Case

Stack
region

GC

RTS

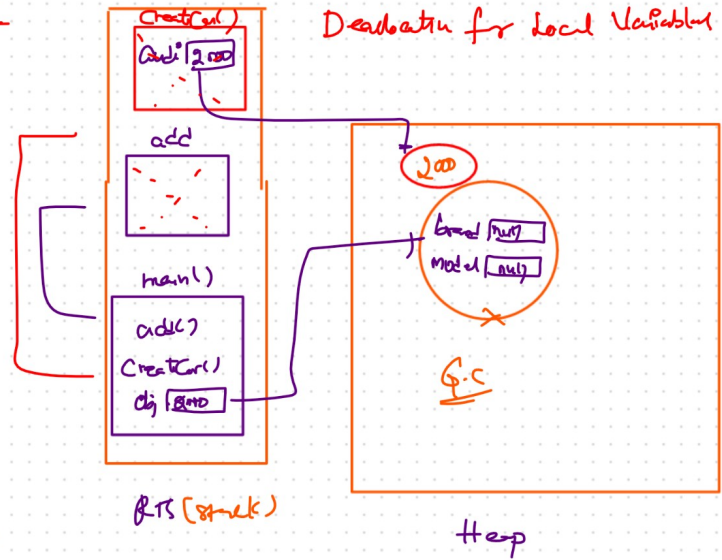

Heap
Deallocation for Local Variables

```

PC -> static void createCar() {
    Car audi = new Car();
}

public static void main(String[] args) {
    add();
    createCar();
}

```

Instance Variable Case

Methods

Structure (Signature)

modifier return-type name(parameters) {exception list}

body

}

Example

void — Nothing return
type — int

Common

do →

```
int add(int a, int b) {  
    int result = a + b;  
    return result;  
}
```

Call

{
 add()
}

{
 add()
}

(2) — 10

— add()

— add()

— add()

Note:

- 1) method is a set of instructions, used to execute multiple times as when required
- 2) methods are used when we have common logic to call multiple times
- 3) methods help in code re-usability & also easy to maintain
